

# SCHEME REVIEW AND LISTS [Meta](#)

---

## COMPUTER SCIENCE MENTORS 61A

November 12 – November 15, 2024

---

### Recommended Timeline

- Apply n: 7 mins
- Scheme Lists Overview: 10 mins
- WWSD – Scheme Lists: 10 mins
- Sixty Ones: 8 mins
- Is Prefix: 10 mins
- Argmax: 15 mins

# 1 Scheme Review

---

1. Define `apply-multiple` which takes in a single argument function `f`, a nonnegative integer `n`, and a value `x` and returns the result of applying `f` to `x` a total of `n` times.

```
;doctests
scm> (apply-multiple (lambda (x) (* x x)) 3 2)
256
scm> (apply-multiple (lambda (x) (+ x 1)) 10 1)
11
scm> (apply-multiple (lambda (x) (* 1000 x)) 0 5)
5
```

```
(define (apply-multiple f n x)
```

```
_____
_____
_____
```

```
)
```

```
(define (apply-multiple f n x)
  (if (= n 0)
      x
      (f (apply-multiple f (- n 1) x)))))
```

Alternate solution:

```
(define (apply-multiple f n x)
  (if (= n 0)
      x
      (apply-multiple f (- n 1) (f x)))))
```

## Teaching Tips

- Functions can get a little confusing to work with in Scheme so it helps to remind your students that they are all just pieces of data.
- Thinking about the base case first may be more helpful with this problem. When do you stop applying your function to the input? How do you know/which input will tell you when to stop? This will then provide a good idea of what the recursive calls should be.
- There are two alternate solutions to this issue that differ in what you call your function `f` on. Go along with whatever your students share and if possible share the alternate solutions so students can see different ways of recursing in Scheme.

## 2 Scheme Lists

Unlike Python, all Scheme lists are linked lists. Recall that, in Python, a linked list is made up of `Links` that each have a `first` and a `rest`, where the `rest` is another `Link`. Similarly, each Scheme list is a “pair” where the first element of the pair is the first element of the list, and the second element of the pair is the rest of the list (also a pair).

We use the `cons` procedure to construct Scheme lists, and `nil` to represent empty lists. The sequence 1, 2, 3 may then be represented as follows:

```
scm> (cons 1 (cons 2 (cons 3 nil)))  
(1 2 3)
```

It's worth pointing out to your students that, unlike with the `Link` class, the `nil` must be explicitly provided at the end of the linked list.

The `car` and `cdr` procedures are used to access the elements of a Scheme list. `car` gets the first element of a list, while `cdr` gets the rest of the list:

```
scm> (define lst (cons 1 (cons 2 (cons 3 nil))))  
lst  
scm> (car lst)  
1  
scm> (cdr lst)  
(2 3)
```

You can make the following analogy between linked lists in Python and Scheme:

<code>Link(1, Link.empty)</code> <code>a = Link(1, Link(2, Link.empty))</code> <code>a.first</code> <code>a.rest</code>	<code>(cons 1 nil)</code> <code>(define a (cons 1 (cons 2 nil)))</code> <code>(car a)</code> <code>(cdr a)</code>
--	--

The `list` procedure and quotation give us additional convenient ways to construct lists:

```
scm> (list 1 2 3)  
(1 2 3)  
scm> '(1 2 3)  
(1 2 3)  
scm> (list 1 (+ 1 1) 3)  
(1 2 3)  
scm> '(1 (+ 1 1) 3)  
(1 (+ 1 1) 3)
```

Note that quotation will prevent any of the list items from being evaluated, which can occasionally be inconvenient.

If relevant, I like to discuss when it makes the most sense to use the different ways of constructing a list.

- `cons` is useful when you have a way to construct the first element and rest of the list, e.g. in recursive problem solving,
- `list` and quotation are useful when you want to hardcode a list into your code beforehand, but typically aren't that useful if you want to dynamically create a list based on program input.

## 2.1 Useful procedures

---

In addition to the procedures mentioned above, the following procedures are often useful when dealing with Scheme lists:

- `(null? s)`: returns true if `s` is `nil`.
- `(length s)`: returns the length of `s`.
- `(append s1 ... sn)`: returns the result of concatenating lists `s1, ..., sn`.
- `(map f s)`: returns the result of applying the procedure `f` to each element of `s`.
- `(filter pred s)`: returns a list containing the elements of `s` for which the single-argument procedure `pred` returns true.
- `(reduce comb s)`: combines the elements of `s` into a single value using the two-argument procedure `comb`.

## 2.2 Equality testing

---

Equality testing in Scheme is a bit confusing as it is handled by three separate procedures:

- `(= a b)`: returns true if `a` equals `b`. Both must be numbers.
- `(eq? a b)`: returns true if `a` and `b` are equivalent primitive values. For two objects, `eq?` returns true if both refer to the exactly same object in memory (like `is` in Python).
- `(equal? a b)`: returns true if `a` and `b` are equivalent. Two lists are equivalent if their elements are equivalent.

### Teaching Tips

- For the love of God, please do not mini-lecture all of this stuff. This information is presented as a reference for you, and you should ask your students what they would like to go over so that you do not waste their time.
- Emphasize to students that Scheme lists are linked lists and NOT Python lists
  - Discuss the limitations (e.g. no indexing) and capabilities (e.g. recursion)
- If you're an old bear<sup>TM</sup>, keep in mind that dotted lists (thank god) have been removed from the curriculum, so Scheme lists have the same functionality as linked lists
- The [61A Scheme Web interpreter](#) is **very useful** for visualizing lists!
- If you choose to give a mini-lecture on Scheme list syntax, try using each keyword in an example instead of just talking about them!

1. What will Scheme output? Draw box-and-pointer diagrams to help determine this. (Ask your mentor if you're unsure what's going on. You aren't expected to understand this completely on your own.)

```
scm> (cons 1 (cons 2 nil))
```

```
(1 2)
```

```
scm> (cons 1 '(2 3 4 5))
```

```
(1 2 3 4 5)
```

When we use the quote before the list, we are saying that we should put the literal list (2 3 4 5) in the cdr of this list. So in this case we create a list where the first element (car) is 1, and the cdr is the list (2 3 4 5).

```
scm> (cons 1 '(2 (cons 3 nil)))
```

```
(1 2 (cons 3 ()))
```

Since we also used a quote here, we do not evaluate the (cons 3 nil). We keep everything inside the quotes the same so the cdr of this list is the list (2 (cons 3 nil)). That means that we add the element 2, and then the nested list (cons 3 nil).

```
scm> (cons 1 (2 (cons 3 nil)))
```

```
eval: bad function in : (2 (cons 3 nil))
```

While evaluating the operands, Scheme will try to evaluate the expression (2 (cons 3 nil)). Since 2 is not a valid operator, this expression Errors.

```
scm> (cons 3 (cons (cons 4 nil) nil))
```

```
(3 (4))
```

```
scm> (define a '(1 2 3))
```

a

Defines a list of elements of (1 2 3) and binds the list to the variable a. Recall that define returns the name of the symbol.

```
scm> a
```

(1 2 3)

```
scm> (car a)
```

1

```
scm> (cdr a)
```

(2 3)

```
scm> (car (cdr a))
```

2

From above, we know that (cdr a) is (2 3). From that, we can evaluate (car (cdr a)) to 2.

How can we get the 3 out of a?

```
(car (cdr (cdr a)))
```

To get to the pair that contains 3, we need to call (cdr (cdr a)). To get the element 3, we need the car of (cdr (cdr a)).

### Teaching Tips

- Draw diagrams or use the [61A Scheme Web interpreter](#) for visualizing lists
- Encourage students to ask questions and experiment with extra cons, car, and cdr statements to see how they change the outputs of statements!
- While unrelated to the problem, it may be helpful to teach students these keywords:
  - (pair? arg), which checks if arg has a first and rest
  - (list? arg), which returns true if arg is a well-formed list

2. Define sixty-ones. Return the number of times that 1 follows 6 in the list.

```
> (sixty-ones '(4 6 1 6 0 1))
1
> (sixty-ones '(1 6 1 4 6 1 6 0 1))
2
> (sixty-ones '(6 1 6 1 4 6 1 6 0 1))
3
```

```
(define (sixty-ones lst)
  (cond (_____ )
        (_____ )
        (else _____)))
```

```
(define (sixty-ones lst)
  (cond ((or (null? lst) (null? (cdr lst))) 0)
        ((and (= 6 (car lst)) (= 1 (cadr lst))) (+ 1 (sixty-ones (cddr lst))))
        (else (sixty-ones (cdr lst)))))
```

Encourage students to think about the logic and solutions in Python first if they seem stuck. Considering developing a Python version of solutions with the students first and walk through 'translating' the

3. Define `is-prefix`, which takes in a list `p` and a list `lst` and determines if `p` is a prefix of `lst`. It determines if `lst` starts with all the elements in `p`.

```
; Doctests:
scm> (is-prefix '() '())
#t
scm> (is-prefix '() '(1 2))
#t
scm> (is-prefix '(1) '(1 2))
#t
scm> (is-prefix '(2) '(1 2))
#f
; Note here p is longer than lst
scm> (is-prefix '(1 2) '(1))
#f
```

[solution to Scheme together.](#) `(define (is-prefix p lst)`

---

---

---

---

---

---

)

```
; is-prefix with nested if statements
(define (is-prefix p lst)
  (if (null? p)
      #t
      (if (null? lst)
          #f
          (and
            (= (car p) (car lst))
            (is-prefix (cdr p) (cdr lst)))))))
```

```
; is-prefix with a cond statement
(define (is-prefix p lst)
  (cond
    ((null? p) #t)
    ((null? lst) #f)
    (else (and (= (car p) (car lst))
                (is-prefix (cdr p) (cdr lst)))))))
```

### Teaching Tips

- Encourage students to think about how they would solve this problem without starter code. How would you determine if a given input matches the first part of another input? Iteration! Then translate this iteration into Scheme.
- Be sure to check for null cases or edge cases, keep track of parentheses, and keep in mind how true and false are represented in Scheme.
- Remind students also that there are two ways to go about checking different cases in Scheme: nested ifs or a cond statement.
- As a hint, also consider suggesting figuring out the logic with pseudo or Python code, then translating into Scheme.

4. Implement `argmax`, a function that takes in a list, `lst`, and returns the index of the largest element in `lst`. If there are two or more elements that are the largest element, return the index of the one that appears first in `lst`.

You can assume all elements of `lst` are non-negative integers, and `lst` has at least 1 element and no nested lists.

```
(define (argmax lst)
  (define (max-helper lst max-so-far max-index curr-index)
    (cond
      (( (_____)) _____)
      (( (_____)) _____)
      (_____))
    (else
     _____))
  )
  (max-helper _____)
)
```

```
(define (argmax lst)
  (define (max-helper lst max-so-far max-index curr-index)
    (cond
      ((null? lst) max-index)
      ((> (car lst) max-so-far)
       (max-helper (cdr lst) (car lst) curr-index (+ curr-index
                                                         1)))
      (else
       (max-helper (cdr lst) max-so-far max-index (+ curr-index
                                                         1))))
    )
  )
  (max-helper lst 0 0 0)
)
```

It's important that students learn how to use helper functions in Scheme; since there is no iteration, most anything that cannot be done through pure recursion will have to be done via a helper function.
