

# HIGHER-ORDER FUNCTIONS & ENVIRONMENT DIAGRAMS Solutions

## COMPUTER SCIENCE MENTORS 61A

February 3 – February 7, 2025

### 1 Environment Diagrams

1. Give the environment diagram and console output that result from running the following code.

```
def swap(x, y):  
    x, y = y, x  
    return print("Swapped!", x, y)
```

```
x, y = 60, 1  
a = swap(x, y)  
swap(a, y)
```

Print output (drag lower right corner to resize)

```
Swapped! 1 60  
Swapped! 1 None
```

f1: swap [parent=Global]

x	1
y	60
Return value	None

f2: swap [parent=Global]

x	1
y	None
Return value	None

2. Draw the environment diagram that results from running the following code.

```
def funny(joke):  
    hoax = joke + 1  
    return funny(hoax)
```

```
def sad(joke):  
    hoax = joke - 1  
    return hoax + hoax
```

```
funny, sad = sad, funny  
result = funny(sad(2))
```

## 2 Higher-Order Functions

1. What are higher-order functions? Why and where do we use lambda and higher-order functions? Can you give a practical example of where we would use a HOF?

Higher-order functions are functions that does at least one of the following: take at least one or more functions as arguments and returns a function. In practice, we use lambda functions to pass code as data in a concise manner. One specific example to illustrate the use of lambdas is the optional `key` parameter for `min` and `max` functions. Lambda functions can be passed as arguments to higher-order functions. Higher order functions serve as a tool of abstraction, allowing us to simplify repeated actions into one function that we can use over and over again. Students can have varying answers for practice uses of HOFs, though here are some suggestions for the average student coming across this worksheet:

- Our method signature is composed of one parameter, but we wish to use a higher order function with more parameters to abstract extra steps.
- When our function is long and complex; easier to read code when it's organized into several different higher order functions.

2. Give the environment diagram and console output that result from running the following code.

```
x = 20
def foo(y):
    x = 5
    if y == 5:
        return lambda y: x + y
    else:
        print('hello!')

y = foo(5)
x = y(7)
z = foo(7)
```

3. Implement compose.

```
def compose(f, g):
    """
    >>> a = compose(lambda x: x * x, lambda x: x + 4)
    >>> a(2)
    36
    """
    return lambda x: f(g(x))
```

4. Write a function, `whole_sum`, which takes in an integer, `n`. It returns another function which takes in an integer, and returns `True` if the digits of that integer sum to `n` and `False` otherwise.

```
def whole_sum(n):  
    """  
    >>> whole_sum(21) (777)  
    True  
    >>> whole_sum(142) (10010101010)  
    False  
    """  
    def check(x):  
  
        _____  
  
        while _____:  
  
            last = _____  
  
            _____  
  
            _____  
  
        return _____  
  
    return _____
```

```
def whole_sum(n):  
    def check(x):  
        total = 0  
        while x > 0:  
            last = x % 10  
            x = x // 10  
            total += last  
        return total == n  
    return check
```

5. Implement `make_alternator` which takes in two functions and outputs a function. The returned function takes in a number `x` and prints out all the numbers from 1 to `x`, applying `f` to the odd numbers and applying `g` to the even numbers before printing.

```
def make_alternator(f, g):  
    """  
    >>> a = make_alternator(lambda x: x * x, lambda x: x + 4)  
    >>> a(5)  
    1  
    6  
    9  
    8  
    25  
    """  
  
    def alternator(x):  
        i = 1  
        while i <= x:  
            if i % 2 == 1:  
                print(f(i))  
            else:  
                print(g(i))  
            i += 1  
        return alternator
```

6. Write a function, `curry_forever`, which takes in a two-argument function, `f`, and an integer, `arg_num`. It returns another function that allows us to enter `arg_num` amount of numbers into `f` one by one.

```
def curry_forever(f, arg_num, base=0):
    """
    >>> g = curry_forever(lambda x, y: x + y, 4)
    >>> g(1)(2)(3)(4) # 1 + 2 + 3 + 4
    10
    """

    def helper(arg_num, amt):

        if arg_num == 0:

            _____

        return _____

    _____

def curry_forever(f, arg_num, base=0):
    def helper(arg_num, amt):
        if arg_num == 0:
            return amt
        return lambda x: helper(arg_num - 1, f(amt, x))
    return helper(arg_num, base)
```
