

HIGHER-ORDER FUNCTIONS & ENVIRONMENT DIAGRAMS

COMPUTER SCIENCE MENTORS 61A

February 3 – February 7, 2025

1 Environment Diagrams

1. Give the environment diagram and console output that result from running the following code.

```
def swap(x, y):  
    x, y = y, x  
    return print("Swapped!", x, y)
```

```
x, y = 60, 1  
a = swap(x, y)  
swap(a, y)
```

2. Draw the environment diagram that results from running the following code.

```
def funny(joke):  
    hoax = joke + 1  
    return funny(hoax)  
  
def sad(joke):  
    hoax = joke - 1  
    return hoax + hoax  
  
funny, sad = sad, funny  
result = funny(sad(2))
```

2 Higher-Order Functions

1. What are higher-order functions? Why and where do we use lambda and higher-order functions? Can you give a practical example of where we would use a HOF?

2. Give the environment diagram and console output that result from running the following code.

```
x = 20
def foo(y):
    x = 5
    if y == 5:
        return lambda y: x + y
    else:
        print('hello!')

y = foo(5)
x = y(7)
z = foo(7)
```

3. Implement `compose`.

```
def compose(f, g):
    """
    >>> a = compose(lambda x: x * x, lambda x: x + 4)
    >>> a(2)
    36
    """
```

4. Write a function, `whole_sum`, which takes in an integer, `n`. It returns another function which takes in an integer, and returns `True` if the digits of that integer sum to `n` and `False` otherwise.

```
def whole_sum(n):  
    """  
    >>> whole_sum(21) (777)  
    True  
    >>> whole_sum(142) (10010101010)  
    False  
    """  
    def check(x):  
  
        _____  
  
        while _____:  
  
            last = _____  
  
            _____  
  
            _____  
  
        return _____  
  
    return _____
```

5. Implement `make_alternator` which takes in two functions and outputs a function. The returned function takes in a number `x` and prints out all the numbers from 1 to `x`, applying `f` to the odd numbers and applying `g` to the even numbers before printing.

```
def make_alternator(f, g):  
    """  
    >>> a = make_alternator(lambda x: x * x, lambda x: x + 4)  
    >>> a(5)  
    1  
    6  
    9  
    8  
    25  
    """
```

6. Write a function, `curry_forever`, which takes in a two-argument function, `f`, and an integer, `arg_num`. It returns another function that allows us to enter `arg_num` amount of numbers into `f` one by one.

```
def curry_forever(f, arg_num, base=0):  
    """  
    >>> g = curry_forever(lambda x, y: x + y, 4)  
    >>> g(1)(2)(3)(4) # 1 + 2 + 3 + 4  
    10  
    """
```

```
    def helper(arg_num, amt):
```

```
        if arg_num == 0:
```

```
            _____  
  
            return _____
```

```
    _____
```
