## PROGRAMS AS DATA, INTERPRETERS & MACROS

## COMPUTER SCIENCE MENTORS 61A

November 18 – November 23, 2024

		1	Interpreters
1.	The following questions refer to the Scheme interpreter. Assume we're using the in lecture and in the Scheme project.	ne ir	
	(a) What's the purpose of the read stage in a Read-Eval-Print Loop? For our Sc does it take in, and what does it return?	cher	ne interpreter, what
	(b) What are the two components of the read stage? What do they do?		
	(c) Write out the constructor for the Pair object that the read stage creates (define (foo x) (+ x 1))	s fro	om the input string

(d) For the previous example, imagine we saved that Pair object to the variable p. How could we check that the expression is a define special form? How would we access the name of the function and the body of the function?

2. Circle or write the number of calls to scheme\_eval and scheme\_apply for the code below.

```
(if 1 (+ 2 3) (/ 1 0))
scheme_eval 1 3 4 6
scheme_apply 1 2 3 4

(or #f (and (+ 1 2) 'apple) (- 5 2))
scheme_eval 6 8 9 10
scheme_apply 1 2 3 4

(define (square x) (* x x))
(+ (square 3) (- 3 2))
scheme_eval 2 5 14 24
scheme_apply 1 2 3 4

(define (add x y) (+ x y))
(add (- 5 3) (or 0 2))
```

2 CSM 61A FALL 2024

1. What will Scheme output?

```
scm> (define x 6)
scm> (define y 1)
scm> '(x y a)
scm> '(,x ,y a)
scm> '(,x y a)
scm> '(,(if (- 1 2) '+ '-) 1 2)
scm> (eval `(,(if (- 1 2) '+ '-) 1 2))
scm> (define (add-expr a1 a2)
              (list '+ a1 a2))
scm> (add-expr 3 4)
scm> (eval (add-expr 3 4))
scm> (define-macro (add-macro a1 a2)
            (list '+ a1 a2))
scm> (add-macro 3 4)
```

2. The built-in apply procedure in Scheme applies a procedure to a given list of arguments. For example, (apply f '(1 2 3)) is equivalent to (f 1 2 3). Write a macro procedure meta-apply, which is similar to apply, except that it works not only for procedures, but also for macros and special forms. That is, (meta-apply operator (operand1 ... operandN)) should be equivalent to (operator operand1 ... operandN) for any operator and operands. See doctests for examples.

```
; Doctests
scm> (meta-apply + (1 2))
3
scm> (meta-apply or (#t (/ 1 0) #f))
#t
(define-macro (meta-apply operator operands)
)
```

3. NAND (not and) is a logical operation that returns false if all of its operands are true, and true otherwise. That is, it returns the opposite of AND. Implement the nand macro procedure below, which takes in a list of expressions and returns the NAND of their values. Similar to **and**, nand should short circuit and return true as soon as it encounters a false operand, evaluating from left to right.

Hint: You may use meta-apply in your implementation.

```
;Doctests
scm> (nand (#t #t #t #t #t #t))
#f
scm> (nand (#t #f #t))
#t
scm> (nand (#f (/ 1 0)))
#t
(define-macro (nand operands))
```

CSM 61A FALL 2024

4. Implement apply-twice, which is a macro that takes in a call expression with a single argument. It should return the result of applying the operator to the operand twice.

```
;Doctests
scm> (define add-one (lambda (x) (+ x 1)))
add-one
scm> (apply-twice (add-one 1))
3
scm> (apply-twice (print 'hi))
hi
undefined
(define-macro (apply-twice call-expr)
)
```

5. Write a macro procedure censor, which takes in an expression expr and a symbol phrase. If expr does not contain any instance of phrase, then censor simply evaluates expr. However, if expr does contain an instance of the censored phrase, the symbol censored is returned and the expression is not evaluated.
