REPRESENTATION, MUTABLE TREES, LINKED LISTS

CSM 61A

March 7 - March 11, 2022

1 Representation

Representation Overview: __repr__ and __str__

Classes can have "magic methods" that add special built-in syntax features. They start and end with double underscores, such as in __init__. The goal of __str__ is to convert an object to a human-readable string. The __str__ function is helpful for printing objects and giving us information that's more readable than __repr__. Whenever we call **print**() on an object, it will call the __str__ method of that object and print whatever value the __str__ call returned. For example, if we had a Person class with a name instance variable, we can create a __str__ method like this:

```python
def __str__(self):
    return "Hello, my name is " + self.name
```

This __str__ method gives us readable information: the person's name. Now, when we call print on a person, the following will happen:

```python
>>> p = Person("John Denero")
>>> str(p)
'Hello, my name is John Denero'
>>> print(p)
Hello, my name is John Denero
```

The __repr__ magic method returns the "official" string representation of an object. You can invoke it directly by calling **repr**(<some **object**>). However, __repr__ doesn't always return something that is easily readable, that is what

__str__ is for. Rather, __repr__ ensures that all information about the object is present in the representation. When you ask Python to represent an object in the Python interpreter, it will automatically call **repr** on that object and then print out the string that **repr** returns. If we were to continue our Person example from above, let's say that we added a **repr** method:

```
def __repr__(self):
    return "Name: " + self.name
```

Then we can write the following code:

```
# Python calls this object's repr function to see what
# to print on the line. Note, Python prints whatever
# result it gets from repr so it removes the quotes
# from the string
>>> p
Name: John Denero

# User is invoking the repr function directly.
# Since the function returns a string, its output
# has quotes. In the previous line, Python called
# repr and then printed the value. This line works
# like a regular function call: if a function
# returns a string, output that string with quotes.
>>> repr(p)
"Name: John Denero"
```

1. **Musician** - What would Python display? Write the result of executing the code and the prompts below. If a function is returned, write "Function". If nothing is returned, write "Nothing". If an error occurs, write "Error".

```python
class Musician:
    popularity = 0
    def __init__(self, instrument):
        self.instrument = instrument
    def perform(self):
        print("a rousing " + self.instrument + " performance")
        self.popularity = self.popularity + 2
    def __repr__(self):
        return self.instrument

class BandLeader(Musician):
    def __init__(self):
        self.band = []
    def recruit(self, musician):
        self.band.append(musician)
    def perform(self, song):
        for m in self.band:
            m.perform()
        Musician.popularity += 1
        print(song)
    def __str__(self):
        return "Here's the band!"
    def __repr__(self):
        band = ""
        for m in self.band:
            band += str(m) + " "
        return band[:-1]

miles = Musician("trumpet")
goodman = Musician("clarinet")
ellington = BandLeader()
```

```
>>> ellington.recruit(goodman)
>>> ellington.perform()
```

```
>>> ellington.perform("sing, sing, sing")
```

```
>>> goodman.popularity, miles.popularity
```

```
>>> ellington.recruit(miles)
>>> ellington.perform("caravan")
```

```
>>> ellington.popularity, goodman.popularity, miles.popularity
```

```
>>> print(ellington)
```

```
>>> ellington
```

2   Mutable Trees

For the following problems, use this definition for the Tree class:

```python
class Tree:
    def __init__(self, label, branches=[]):
        self.label = label
        self.branches = list(branches)

    def is_leaf(self):
        return not self.branches

    def __repr__(self):
        if self.branches:
            branch_str = ', ' + repr(self.branches)
        else:
            branch_str = ''
        return 'Tree({0}{1})'.format(self.label, branch_str)
```

- The constructor constructs and returns a new instance of `Tree`

    ```python
    t = Tree(1)#creates a Tree instance with label 1 and no branches
    , since branches is defaulted to []
    ```

- The `label` and `branches` are attributes, and `is_leaf()` is a method of the class.

    ```python
    t.label #returns the label of the tree
    ```

    ```python
    t.branches #returns the branches of the tree, which is a list
     of trees
    ```

    ```python
    t.is_leaf()#returns True if the tree is a leaf
    ```

- A tree object is mutable

    To modify a `Tree` object, simply reassign its attributes. For example, `t.label = 2`.

    This means we can mutate values in the tree object instead of making a new tree that we return. In other words, we can solve tree class problems non-destructively and destructively.

1. Implement `tree_sum` which takes in a Tree object and replaces the label of the tree with the sum of all the values in the tree. `tree_sum` should also return the new label.

```
def tree_sum(t):
    """
    >>> t = Tree(1, [Tree(2, [Tree(3)]), Tree(4)])
    >>> tree_sum(t)
    10
    >>> t.label
    10
    >>> t.branches[0].label
    5
    >>> t.branches[1].label
    4
    """
```

2. DoubleTree hired you to architect one of their hotel expansions! As you might expect, their floor plan can be modeled as a tree and the expansion plan requires doubling each node (the patented double tree floor plan). Here's what some sample expansions look like:

Before   **After**
Fill in the implementation for `double_tree`.

```python
def double_tree(t):
    """
    Given a tree, return a new tree where entries appear
    twice.
    >>> double_tree(Tree(1))
    Tree(1, [Tree(1)])
    >>> double_tree(Tree(1, [Tree(2), Tree(3)]))
    Tree(1, [Tree(1, [Tree(2, [Tree(2)]),
                      Tree(3, [Tree(3)])
                     ])
            ])
    """
```

3   Linked Lists

Linked lists consists of a series of links which have two attributes: `first` and `rest`. The `first` attribute contains the value of the link (which can be an integer, string, list, even another linked list!). The `rest` attribute, on the other hand, is a pointer to another link or `Link.empty`, which is just an empty linked list represented traditionally by an empty tuple (but not necessarily, so never assume that it is represented by an empty tuple otherwise you will break an abstraction barrier!).

Because each link contains another link or `Link.empty`, linked lists lend themselves to recursion (just like trees). Consider the following example, in which we double every value in linked list. We mutate the current link and then recursively double the rest.

```python
def double_values(link):
    if link is not Link.empty:
        link.first *= 2 # we mutate the value inside of the link
        double_val(link.rest) # we mutate the values in the rest
                              # of the linked list
    # if the link is empty then do nothing
```

However, unlike with trees, we can also solve many linked list questions using iteration. Take the following example where we have written `double_values` using a while loop instead of using recursion:

```python
def double_values_iter(link):
    while link is not Link.empty:
        link.first *= 2
        link = link.rest # Note that this does not mutate
                         # the original linked list;
                         # it changes what link the variable
                         # link is pointing to
```

For each of the following problems, assume linked lists are defined as follows:

```python
class Link:
    empty = ()
    def __init__(self, first, rest=empty):
        assert rest is Link.empty or isinstance(rest, Link)
        self.first = first
        self.rest = rest

    def __repr__(self):
        if self.rest is not Link.empty:
            rest_repr = ', ' + repr(self.rest)
        else:
            rest_repr = ''
        return 'Link(' + repr(self.first) + rest_repr + ')'

    def __str__(self):
        string = '<'
        while self.rest is not Link.empty:
            string += str(self.first) + ' '
            self = self.rest
        return string + str(self.first) + '>'
```

To check if a Link is empty, compare it against the class attribute Link.empty:

```python
if link is Link.empty:
    print('This linked list is empty!')
```

1. What will Python output? Draw box-and-pointer diagrams to help determine this.

```
>>> a = Link(1, Link(2, Link(3)))
>>> a.first
```

```
>>> a.first = 5
>>> a.first
```

```
>>> a.rest.first
```

```
>>> a.rest.rest.rest.rest.first
```

```
>>> a.rest.rest.rest = a
>>> a.rest.rest.rest.rest.first
```

```
>>> repr(Link(1, Link(2, Link(3, Link.empty))))
```

```
>>> Link(1, Link(2, Link(3, Link.empty)))
```

```
>>> str(Link(1, Link(2, Link(3))))
```

```
>>> print(Link(Link(1), Link(2, Link(3))))
```

2. Write a function `skip`, which takes in a `Link` and returns a new `Link` with every other element skipped.

```
def skip(lst):
    """
    >>> a = Link(1, Link(2, Link(3, Link(4))))
    >>> a
    Link(1, Link(2, Link(3, Link(4))))
    >>> b = skip(a)
    >>> b
    Link(1, Link(3))
    >>> a
    Link(1, Link(2, Link(3, Link(4)))) # Original is unchanged
    """
    if _____:

        _____

    elif _____:

        _____

    _____
```

3. Now write function `skip` by mutating the original list, instead of returning a new list. Do NOT call the `Link` constructor.

```
def skip(lst):
    """
    >>> a = Link(1, Link(2, Link(3, Link(4))))
    >>> skip(a)
    >>> a
    Link(1, Link(3))
    """
```

4. **(Optional)** Write `has_cycle` which takes in a `Link` and returns `True` if and only if there is a cycle in the `Link`. Note that the cycle may start at any node and be of any length. Try writing a solution that keeps track of all the links we've seen. Then try to write a solution that doesn't store those witnessed links (consider using two pointers!).

```python
def has_cycle(s):
    """
    >>> has_cycle(Link.empty)
    False
    >>> a = Link(1, Link(2, Link(3)))
    >>> has_cycle(a)
    False
    >>> a.rest.rest.rest = a
    >>> has_cycle(a)
    True
    """
```
